We'll cover both differential calculus (derivatives) and integral calculus (integrals), touching upon their fundamental applications. Get ready to build your confidence, one problem at a time!

Understanding the Building Blocks: Derivatives

Derivatives are the cornerstone of differential calculus. They measure the instantaneous rate of change of a function. In simpler terms, they tell us how something is changing at a specific point. This concept is crucial in physics, economics, engineering, and countless other fields.

Example 1: Finding the Velocity of a Moving Object

Imagine a particle moving along a straight line. Its position, s , at any given time t is described by the function $s(t) = 3t^2 - 5t + 2$, where s is in meters and t is in seconds. We want to find the velocity of the particle at $t = 4$ seconds.

The Concept: Velocity is the rate of change of position with respect to time. In calculus terms, this means velocity is the derivative of the position function.

The Solution:

- Find the derivative of the position function, $s(t)$. We use the power rule for differentiation, which states that if $f(x) = ax^n$, then $f'(x) = n \cdot ax^{(n-1)}$.
 $s'(t) = \frac{d}{dt}(3t^2 - 5t + 2)$
 $s'(t) = \frac{d}{dt}(3t^2) - \frac{d}{dt}(5t) + \frac{d}{dt}(2)$
 $s'(t) = (2 \cdot 3t^{(2-1)}) - (1 \cdot 5t^{(1-1)}) + 0$
 $s'(t) = 6t - 5$
- Evaluate the derivative at $t = 4$ seconds. Substitute $t = 4$ into the velocity function $v(t) = s'(t)$.
 $v(4) = 6 \cdot 4 - 5$
 $v(4) = 24 - 5$
 $v(4) = 19$

The Answer: The velocity of the particle at $t = 4$ seconds is 19 meters per second. This means that at that precise moment, the particle is moving forward at a speed of 19 m/s.

Example 2: Determining the Slope of a Tangent Line

Let's say we have a curve defined by the function $f(x) = x^3 - 2x^2 + x - 1$. We want to find the slope of the tangent line to this curve at the point where $x = 2$.

The Concept: The derivative of a function at a specific point gives us the slope of the tangent line at that point. The tangent line is a straight line that "just touches" the curve at that single point.

The Solution:

- Find the derivative of the function, $f(x)$. Again, we'll use the power rule.
 $f'(x) = \frac{d}{dx}(x^3 - 2x^2 + x - 1)$
 $f'(x) = \frac{d}{dx}(x^3) - \frac{d}{dx}(2x^2) + \frac{d}{dx}(x) - \frac{d}{dx}(1)$
 $f'(x) = 3x^{(3-1)} - (2 \cdot 2x^{(2-1)}) + 1x^{(1-1)} - 0$
 $f'(x) = 3x^2 - 4x + 1$
- Evaluate the derivative at $x = 2$. Substitute $x = 2$ into the derivative function.
 $f'(2) = 3 \cdot (2)^2 - 4 \cdot (2) + 1$
 $f'(2) = 3 \cdot 4 - 8 + 1$
 $f'(2) = 12 - 8 + 1$
 $f'(2) = 5$

The Answer: The slope of the tangent line to the curve $f(x) = x^3 - 2x^2 + x - 1$ at $x = 2$ is 5.

Exploring the Power of Accumulation: Integrals

Integrals are the flip side of derivatives. While derivatives measure rates of change, integrals allow us to "undo" differentiation and find the accumulated change or the area under a curve. This is fundamental to calculating volumes, work done, and total quantities.

Example 3: Calculating the Area Under a Curve

Let's find the area of the region bounded by the curve $y = x^2$, the x-axis, and the vertical lines $x = 1$ and $x = 3$.

The Concept: The definite integral of a function $f(x)$ from a to b represents the area under the curve $y = f(x)$ between the points $x = a$ and $x = b$.

The Solution:

- Set up the definite integral. We need to integrate the function $f(x) = x^2$ from $x = 1$ to $x = 3$.
 $\text{Area} = \int_{\text{from } 1 \text{ to } 3} x^2 \, dx$
- Find the antiderivative (or indefinite integral) of x^2 . The power rule for integration states that the integral of ax^n is $\frac{a}{(n+1)} \cdot x^{(n+1)} + C$ (where C is the constant of integration for indefinite integrals). For definite integrals, we don't need the $+ C$. The antiderivative of x^2 is $\frac{1}{(2+1)} \cdot x^{(2+1)} = \frac{1}{3}x^3$.
- Evaluate the antiderivative at the upper and lower limits and subtract. This is done using the Fundamental Theorem of Calculus.
 $\text{Area} = \left[\frac{1}{3}x^3 \right]$

[evaluated from 1 to 3]` `Area = $((\frac{1}{3})*(3)^3) - ((\frac{1}{3})*(1)^3)$ ` `Area = $((\frac{1}{3})*27) - ((\frac{1}{3})*1)$ ` `Area = 9 - $(\frac{1}{3})$ ` `Area = $\frac{27}{3} - \frac{1}{3}$ ` `Area = $\frac{26}{3}$ ` **The Answer:** The area under the curve $y = x^2$ between $x = 1$ and $x = 3$ is $\frac{26}{3}$ square units.

Example 4: Finding the Total Distance Traveled

Suppose a car's velocity is given by the function $v(t) = 3t + 2$, where v is in meters per second and t is in seconds. We want to find the total distance the car travels from $t = 0$ to $t = 5$ seconds.

The Concept: Distance is the accumulation of velocity over time. If the velocity is always positive, the total distance traveled is the definite integral of the velocity function. (Note: If velocity could be negative, we'd need to consider the absolute value for total distance, but in this simple case, it's straightforward). **The Solution:** 1. **Set up the definite integral:** We need to integrate the velocity function $v(t) = 3t + 2$ from $t = 0$ to $t = 5$. Distance = $\int_{\text{from } 0 \text{ to } 5} (3t + 2) dt$ 2. **Find the antiderivative of $(3t + 2)$:** Using the power rule for integration: The antiderivative of $3t$ is $\frac{3}{(1+1)} t^{(1+1)} = \frac{3}{2}t^2$. The antiderivative of 2 is $2t$. So, the antiderivative of $3t + 2$ is $\frac{3}{2}t^2 + 2t$. 3. **Evaluate the antiderivative at the limits and subtract:** Distance = $[\frac{3}{2}t^2 + 2t]$ [evaluated from 0 to 5]` `Distance = $((\frac{3}{2})*(5)^2 + 2*5) - ((\frac{3}{2})*(0)^2 + 2*0)$ ` `Distance = $((\frac{3}{2})*25 + 10) - (0 + 0)$ ` `Distance = $(\frac{75}{2} + 10)$ ` `Distance = $37.5 + 10$ ` `Distance = 47.5` **The Answer:** The car travels a total distance of 47.5 meters from $t = 0$ to $t = 5$ seconds.

Calculus in Action: Real-World Applications

The beauty of calculus lies in its ability to model and solve problems in the real world. Here are a few more examples that illustrate its power:

Example 5: Optimization - Maximizing Profit

A company sells widgets. The profit P (in dollars) made from selling x thousand widgets is given by the function $P(x) = -x^3 + 12x^2 - 36x + 50$. We want to find the number of widgets that maximizes the profit. **The Concept:** To find the maximum or minimum of a function (optimization problems), we use derivatives. We find the critical points by setting the first derivative equal to zero and solving for x . Then, we often use the second derivative test to confirm if these points are maxima or minima. **The Solution:** 1. **Find the first derivative of the profit function, $P(x)$:** $P'(x) = \frac{d}{dx} (-x^3 + 12x^2 - 36x + 50)$ ` ` $P'(x) = -3x^2 + 24x - 36$ 2. **Set the first derivative to zero and solve for x :** $-3x^2 + 24x - 36 = 0$ ` Divide by -3 to simplify:  $x^2 - 8x + 12 = 0$ ` Factor the quadratic equation: $(x - 2)(x - 6) = 0$ ` So,  $x = 2$  or  $x = 6$ . These are our critical points. 3. **Find the second derivative of  $P(x)$ :**  $P''(x) = \frac{d}{dx} (-3x^2 + 24x - 36)$ ` ` $P''(x) = -6x + 24$ 4. **Use the second derivative test:** * At $x = 2$: $P''(2) = -6(2) + 24 = -12 + 24 = 12$. Since $P''(2) > 0$, this indicates a local minimum. * At $x = 6$: $P''(6) = -6(6) + 24 = -36 + 24 = -12$. Since $P''(6) < 0$, this indicates a local maximum. **The Answer:** The company maximizes its profit when it sells 6 thousand widgets.

Example 6: Related Rates - Changing Volumes

Imagine a spherical balloon being inflated. The radius r of the balloon is increasing at a rate of 2 cm/s. We want to find the rate at which the volume V of the balloon is increasing when the radius is 10 cm. **The Concept:** Related rates problems involve finding the rate of change of one quantity in terms of the rate of change of another quantity. We use implicit differentiation and the chain rule.

The Solution: 1. **Identify the relevant formulas:** The volume of a sphere is $V = \frac{4}{3}\pi r^3$. 2. **Differentiate both sides of the formula with respect to time (t):** $\frac{d}{dt} (V) = \frac{d}{dt} (\frac{4}{3}\pi r^3)$ ` ` $\frac{dV}{dt} = \frac{4}{3}\pi * \frac{d}{dt} (r^3)$ ` Using the chain rule:  $\frac{d}{dt} (r^3) = 3r^2 * \frac{dr}{dt}$ ` So, $\frac{dV}{dt} = \frac{4}{3}\pi * (3r^2 * \frac{dr}{dt})$

$\frac{dr}{dt}$)` $\frac{dV}{dt} = 4\pi r^2 * \frac{dr}{dt}$ 3. ****Plug in the given values:**** We are given $\frac{dr}{dt} = 2$ cm/s and we want to find $\frac{dV}{dt}$ when $r = 10$ cm. $\frac{dV}{dt} = 4\pi(10 \text{ cm})^2 * (2 \text{ cm/s})$ $\frac{dV}{dt} = 4\pi(100 \text{ cm}^2) * (2 \text{ cm/s})$ $\frac{dV}{dt} = 800\pi \text{ cm}^3/\text{s}$ ****The Answer:**** The volume of the balloon is increasing at a rate of 800π cubic centimeters per second when the radius is 10 cm.

Exploring Examples of Calculus Problems with Answers: A Deep Dive

Calculus, the mathematical discipline focused on change and motion, forms the backbone of numerous scientific, engineering, and economic advancements. At its core, calculus introduces concepts such as differentiation and integration—tools that allow us to model and solve dynamic real-world phenomena. While theoretical, these principles are brought to life through well-structured problems that not only challenge understanding but also reinforce mastery. This article explores a range of classic calculus problems, complete with detailed solutions, to illustrate how the subject operates and why it remains indispensable.

Differentiation: Rate of Change in Action

One of the most fundamental concepts in calculus is differentiation—the process of finding the rate at which a function changes at any given point. Consider the function $f(x) = x^2$. To find its derivative, we apply the power rule, which states that the derivative of x^n is nx^{n-1} . Thus, the derivative $f'(x) = 2x$ reveals that the slope of the curve at any x is precisely twice the input value. A practical example involves modeling the velocity of an object. If position is given by $s(t) = 3t^2 + 2t + 1$, where t is time in seconds, the velocity $v(t) = s'(t) = 6t + 2$. At $t = 4$ seconds, the instantaneous velocity is 26 m/s—a direct application of differentiation in physics. Solving such problems strengthens the ability to interpret dynamic systems, from vehicle motion to population growth, where instantaneous change is critical. This insight enables engineers and scientists to predict behavior, optimize performance, and design safer, more efficient processes.

Integration: Accumulating Change Over Intervals

While differentiation focuses on rates, integration captures accumulation—finding total change over an interval. The integral of a function represents the area under its curve, offering a way to quantify total quantities like distance traveled or accumulated charge. For instance, integrating $f(x) = 2x$ from 0 to 3

yields $\int_0^3 2x \, dx = [x^2]_0^3 = 9$. This result reflects the total area under the line from $x = 0$ to $x = 3$, equivalent to the object's displacement if initial velocity is zero and acceleration is constant. In practical contexts, integration supports modeling continuous processes such as water flow in pipes, electrical current over time, or cumulative financial interest. By translating discrete changes into continuous summation, integration enables precise predictions and informed decision-making across industries.

Applications Beyond the Classroom

The true power of calculus shines through its applications. In medicine, derivatives model drug concentration in the bloodstream, helping determine optimal dosing schedules. Integration calculates total drug exposure over time, minimizing toxicity risks. In finance, integrals compute present and future values of cash flows, guiding investment strategies. Engineers rely on calculus to design bridges, aircraft, and circuits by analyzing stress, aerodynamics, and signal behavior. These examples underscore how calculus transcends abstract math, becoming a vital toolkit for solving complex, real-world problems.

Benefits of Mastering Calculus Problems

Engaging with calculus problems cultivates analytical thinking, problem-solving agility, and logical precision. Students and professionals alike develop the capacity to break down complexity into manageable components, a skill valuable far beyond mathematics. The ability to model change fosters innovation, enabling thinkers to anticipate trends, optimize systems, and drive technological progress. Moreover, the discipline builds resilience. Tackling challenging problems strengthens perseverance and attention to detail—traits essential in any field requiring critical thinking and creativity.

The Future of Calculus in a Digital Age

As technology evolves, calculus remains a cornerstone of scientific advancement. Machine learning, for example, depends heavily on differentiation to minimize error functions and refine models. Quantum computing and complex simulations leverage integrals to manage continuous variables across vast datasets. Meanwhile, educational tools increasingly use interactive platforms to visualize calculus concepts, making abstract ideas tangible through dynamic graphs and real-time feedback. Looking ahead, the integration of calculus with artificial intelligence and big data will deepen its impact, enabling smarter predictions, more accurate simulations, and breakthroughs in fields from climate science to genomics. The foundational problems studied today will continue to inspire tomorrow's innovators. In essence, understanding calculus through example problems not only builds technical skill but also nurtures a mindset ready to navigate and shape an ever-evolving, data-driven world.

We'll cover common problem types, including derivatives, integrals, limits, and applications like optimization and related rates.

Understanding the Building Blocks: Limits and Continuity

Before diving into derivatives and integrals, it's crucial to grasp the concept of limits. Limits form the bedrock of calculus, defining continuity and enabling us to understand the behavior of functions as they approach a specific value. While not always explicitly tested as standalone problems in introductory courses, a solid understanding of limits is paramount for solving more complex calculus questions.

Example 1: Evaluating a Limit Algebraically

Problem: Evaluate the limit: $\lim_{x \rightarrow 3} \frac{x^2 - 9}{x - 3}$

Analysis: If we directly substitute $(x = 3)$ into the expression, we get $\frac{0}{0}$, which is an indeterminate form. This signals that we need to manipulate the expression to simplify it before evaluating the limit. This is a common scenario in limit problems.

Solution:

1. Factor the numerator: The numerator, $(x^2 - 9)$, is a difference of squares and can be factored as $(x - 3)(x + 3)$.
2. Rewrite the expression: The expression becomes $\frac{(x - 3)(x + 3)}{x - 3}$.
3. Cancel common factors: For $(x \neq 3)$, we can cancel the $(x - 3)$ term from the numerator and denominator, leaving $(x + 3)$.
4. Evaluate the simplified limit: Now, we can substitute $(x = 3)$ into the simplified expression $(x + 3)$.

So, $\lim_{x \rightarrow 3} (x + 3) = 3 + 3 = 6$.

Answer: The limit is 6.

Example 2: Limit Using L'Hôpital's Rule

Problem: Evaluate the limit: $\lim_{x \rightarrow 0} \frac{\sin(x)}{x}$

Analysis: Direct substitution yields $\frac{0}{0}$. This indeterminate form allows us to use L'Hôpital's Rule, a powerful technique for evaluating limits of fractions that result in indeterminate forms. This rule states that if $\lim_{x \rightarrow c} \frac{f(x)}{g(x)}$ results in $\frac{0}{0}$ or $\frac{\infty}{\infty}$, then the limit is equal to $\lim_{x \rightarrow c} \frac{f'(x)}{g'(x)}$, provided the latter limit exists.

Solution:

1. Identify $f(x)$ and $g(x)$: Here, $f(x) = \sin(x)$ and $g(x) = x$.
2. Find the derivatives: $f'(x) = \cos(x)$ and $g'(x) = 1$.
3. Apply L'Hôpital's Rule: We evaluate the limit of the ratio of the derivatives: $\lim_{x \rightarrow 0} \frac{\cos(x)}{1}$.
4. Evaluate the new limit: Substituting $x = 0$ into $\cos(x)$ gives $\cos(0) = 1$.

Answer: The limit is 1.

Mastering Derivatives: The Essence of Instantaneous Change

Derivatives are arguably the most iconic concept in calculus. They measure the instantaneous rate of change of a function, providing insights into slopes of tangent lines, velocities, and acceleration. Understanding derivative rules and applications is fundamental to solving a wide array of calculus problems.

Understanding Derivatives: The Power Rule and Beyond

The power rule is a cornerstone for differentiating polynomial functions. For a function of the form $f(x) = ax^n$, its derivative is $f'(x) = n \cdot ax^{n-1}$. Other crucial rules include the product rule, quotient rule, and chain rule, essential for differentiating more complex functions.

Example 3: Applying the Power Rule and Sum/Difference Rule

Problem: Find the derivative of $f(x) = 3x^4 - 2x^3 + 5x - 7$.

Analysis: This problem requires the application of the power rule to each term and the sum/difference rule, which states that the derivative of a sum or difference of functions is the sum or difference of their derivatives. The derivative of a constant is zero.

Solution:

1. Apply the power rule to each term:
 1. Derivative of $3x^4$: $4 \cdot 3x^{4-1} = 12x^3$
 2. Derivative of $-2x^3$: $3 \cdot (-2)x^{3-1} = -6x^2$
 3. Derivative of $5x$: $1 \cdot 5x^{1-1} = 5x^0 = 5$
 4. Derivative of -7 : 0
2. Combine the derivatives of each term:

$$f'(x) = 12x^3 - 6x^2 + 5 - 0$$

Answer: $f'(x) = 12x^3 - 6x^2 + 5$

Example 4: Using the Product Rule

Problem: Find the derivative of $g(x) = (x^2 + 1)(e^x)$.

Analysis: This function is a product of two simpler functions, $u(x) = x^2 + 1$ and $v(x) = e^x$. The product rule states that if $h(x) = u(x)v(x)$, then $h'(x) = u'(x)v(x) + u(x)v'(x)$. We will need to find the derivatives of $u(x)$ and $v(x)$.

Solution:

1. Identify $u(x)$ and $v(x)$: $u(x) = x^2 + 1$, $v(x) = e^x$.
2. Find their derivatives:
 1. $u'(x) = 2x$ (using the power rule and constant rule)
 2. $v'(x) = e^x$ (the derivative of e^x is itself)
3. Apply the product rule formula:

$$g'(x) = (2x)(e^x) + (x^2 + 1)(e^x)$$

4. Simplify the expression (optional but good practice):

$$g'(x) = e^x(2x + x^2 + 1) = e^x(x^2 + 2x + 1) = e^x(x + 1)^2$$

Answer: $g'(x) = e^x(x + 1)^2$

Example 5: Applying the Chain Rule

Problem: Find the derivative of $h(x) = \sin(3x^2)$.

Analysis: This is a composite function, meaning one function is "inside" another. Here, the outer function is $\sin(u)$ and the inner function is $u = 3x^2$. The chain rule is used for differentiating composite functions: if $y = f(g(x))$, then $y' = f'(g(x)) \cdot g'(x)$. This rule is fundamental for understanding complex derivative calculations.

Solution:

1. Identify the outer and inner functions:
 1. Outer function: $f(u) = \sin(u)$, so $f'(u) = \cos(u)$.
 2. Inner function: $g(x) = 3x^2$, so $g'(x) = 6x$.
2. Apply the chain rule:

$$h'(x) = f'(g(x)) \cdot g'(x) = \cos(3x^2) \cdot (6x)$$

3. Rewrite in standard form:

$$h'(x) = 6x \cos(3x^2)$$

Answer: $h'(x) = 6x \cos(3x^2)$

The Power of Integration: Accumulating Change

Integration is the inverse operation of differentiation. It's used to find areas under curves, volumes of solids, and to accumulate quantities over intervals. Understanding indefinite and definite integrals is crucial for solving many application-based calculus problems.

Indefinite Integrals: Finding Antiderivatives

An indefinite integral of a function $f(x)$ is a family of functions whose derivative is $f(x)$. It is denoted by $\int f(x) \, dx$. Remember to always add the constant of integration, $(+ C)$, because the derivative of a constant is zero.

Example 6: Basic Integration using the Power Rule for Integration

Problem: Find the indefinite integral of $f(x) = 5x^2 + \sqrt{x} - \frac{1}{x^3}$.

Analysis: This problem requires rewriting the terms in power form (x^n) and then applying the power rule for integration: $\int x^n dx = \frac{x^{n+1}}{n+1} + C$ (for $n \neq -1$). The integral of $\frac{1}{x}$ is $\ln|x| + C$.

Solution:

1. Rewrite the function in power form:

$$f(x) = 5x^2 + x^{1/2} - x^{-3}$$

2. Integrate each term using the power rule for integration:

1. Integral of $(5x^2)$: $5 \cdot \frac{x^{2+1}}{2+1} = 5 \cdot \frac{x^3}{3} = \frac{5}{3}x^3$

2. Integral of $(x^{1/2})$: $\frac{x^{1/2+1}}{1/2+1} = \frac{x^{3/2}}{3/2} = \frac{2}{3}x^{3/2}$

3. Integral of $(-x^{-3})$: $(-\frac{x^{-3+1}}{-3+1}) = -\frac{x^{-2}}{-2} = \frac{1}{2}x^{-2} = \frac{1}{2x^2}$

3. Add the constant of integration:

$$\int (5x^2 + x^{1/2} - x^{-3}) dx = \frac{5}{3}x^3 + \frac{2}{3}x^{3/2} + \frac{1}{2x^2} + C$$

Answer: $\frac{5}{3}x^3 + \frac{2}{3}x^{3/2} + \frac{1}{2x^2} + C$

Example 7: Definite Integrals and the Fundamental Theorem of Calculus

Problem: Evaluate the definite integral $\int_1^3 (2x + 1) dx$.

Analysis: The Fundamental Theorem of Calculus Part 2 states that if $F(x)$ is an antiderivative of $f(x)$, then $\int_a^b f(x) dx = F(b) - F(a)$. We first find the antiderivative of $(2x + 1)$, and then evaluate it at the upper and lower limits of integration.

Solution:

1. Find the antiderivative of $f(x) = 2x + 1$:

The antiderivative is $F(x) = x^2 + x$.

2. Evaluate $F(x)$ at the upper limit ($x = 3$):

$$F(3) = (3)^2 + 3 = 9 + 3 = 12$$

3. Evaluate $F(x)$ at the lower limit ($x = 1$):

$$F(1) = (1)^2 + 1 = 1 + 1 = 2$$

4. Subtract the lower limit value from the upper limit value:

$$\int_1^3 (2x + 1) dx = F(3) - F(1) = 12 - 2 = 10$$

Answer: 10. This value represents the area under the line $(y = 2x + 1)$ from $(x = 1)$ to $(x = 3)$.

Applications of Calculus: Solving Real-World Problems

Calculus isn't just an abstract mathematical pursuit; it has profound real-world applications. Two common areas where calculus is applied are optimization and related rates.

Optimization Problems: Finding Maxima and Minima

Optimization problems involve finding the maximum or minimum value of a function, often within certain constraints. This typically involves finding critical points by setting the first derivative to zero and analyzing the second derivative to determine if it's a maximum or minimum.

Example 8: Maximizing Area of a Rectangular Pen

Problem: A farmer has 2400 feet of fencing and wants to fence off a rectangular field that borders a straight river. He needs no fence along the river. What are the dimensions of the field that has the largest area?

Analysis: We need to express the area of the rectangle as a function of one variable and then find its maximum. This will involve setting up equations for the perimeter and area, using one to eliminate a variable in the other, and then using calculus to find the maximum.

Solution:

1. Set up variables: Let (l) be the length of the side parallel to the river, and (w) be the width of the sides perpendicular to the river.
2. Formulate the constraint equation (fencing): The total fencing used is $(l + 2w = 2400)$.
3. Formulate the objective function (area): The area is $(A = l \cdot w)$.
4. Express the objective function in terms of one variable: From the constraint, $(l = 2400 - 2w)$. Substitute this into the area formula:

$$(A(w) = (2400 - 2w)w = 2400w - 2w^2)$$

5. Find the critical points: Take the derivative of $(A(w))$ with respect to (w) and set it to zero:

$$(A'(w) = 2400 - 4w)$$

$$(2400 - 4w = 0 \implies 4w = 2400 \implies w = 600)$$

6. Determine if it's a maximum: Use the second derivative test. $(A''(w) = -4)$. Since $(A''(600) = -4 < 0)$, this indicates a local maximum.
7. Find the dimensions: If $(w = 600)$ feet, then $(l = 2400 - 2(600) = 2400 - 1200 = 1200)$ feet.

Answer: The dimensions of the field that has the largest area are 1200 feet (parallel to the river) by 600 feet (perpendicular to the river).

Related Rates Problems: Connecting Rates of Change

Related rates problems involve finding the rate at which a quantity changes with respect to time, given the rates of change of other related quantities. These problems often involve implicit differentiation and the chain rule.

Example 9: The Ladder Problem

Problem: A ladder 10 feet long rests against a vertical wall. If the bottom of the ladder slides away from the wall at a rate of 2 ft/sec, how fast is the top of the ladder sliding down the wall when the bottom of the ladder is 6 feet from the wall?

Analysis: We can model this situation with a right triangle, where the ladder is the hypotenuse. We'll use the Pythagorean theorem and implicitly differentiate with respect to time to find the relationship between the rates of change.

Solution:

1. Set up variables: Let x be the distance of the bottom of the ladder from the wall, and y be the height of the top of the ladder on the wall. The length of the ladder is constant at 10 feet.
2. Formulate the relationship: By the Pythagorean theorem, $x^2 + y^2 = 10^2 = 100$.
3. Identify the given rates and what needs to be found:
 1. Given: $\frac{dx}{dt} = 2$ ft/sec (the rate at which the bottom slides away).
 2. To find: $\frac{dy}{dt}$ (the rate at which the top slides down) when $x = 6$ feet.
4. Implicitly differentiate the equation with respect to time t :

$$\frac{d}{dt}(x^2 + y^2) = \frac{d}{dt}(100)$$

$$2x \frac{dx}{dt} + 2y \frac{dy}{dt} = 0$$

5. Find the value of y when $x = 6$: Using $x^2 + y^2 = 100$, when $x = 6$, $6^2 + y^2 = 100 \implies 36 + y^2 = 100 \implies y^2 = 64 \implies y = 8$ feet (since height must be positive).
6. Substitute the known values into the differentiated equation:

$$2(6)(2) + 2(8)\frac{dy}{dt} = 0$$

$$24 + 16\frac{dy}{dt} = 0$$

7. Solve for $\frac{dy}{dt}$:

$$16\frac{dy}{dt} = -24 \implies \frac{dy}{dt} = -\frac{24}{16} = -\frac{3}{2} \text{ ft/sec.}$$

Answer: The top of the ladder is sliding down the wall at a rate of $-\frac{3}{2}$ ft/sec.

Questions & Answers About examples of calculus problems with answers

No	Question	Answer
1	What's a common real-world calculus problem involving optimization, and how would you solve it?	Optimization problems often involve maximizing profit or minimizing cost. For example, a company wants to find the production level that maximizes its profit. You'd set up a profit function, find its derivative, set the derivative to zero to find critical points, and then use the second derivative test to confirm if it's a maximum.

2	Can you give an example of a related rates problem in calculus and its solution approach?	Related rates problems deal with how the rates of change of different variables are connected. Imagine a spherical balloon being inflated. You're given the rate at which the volume is increasing and asked to find the rate at which the radius is increasing at a specific moment. The solution involves differentiating the volume formula ($V = (4/3)\pi r^3$) implicitly with respect to time (t), substituting known values, and solving for the unknown rate (dr/dt).
3	What's a typical area-under-the-curve problem in calculus, and how is it solved?	Finding the area under a curve is a fundamental application of integration. For instance, you might need to calculate the area between the curve $y = x^2$ and the x-axis from $x=0$ to $x=2$. The solution is to set up a definite integral: $\int_{\text{from } 0 \text{ to } 2} x^2 dx$. Evaluating this integral gives you the exact area.
4	How does calculus help us understand motion, and can you provide a simple example?	Calculus is essential for kinematics. Velocity is the derivative of position with respect to time, and acceleration is the derivative of velocity. If an object's position is given by $s(t) = t^3 - 2t + 5$, its velocity is $v(t) = s'(t) = 3t^2 - 2$, and its acceleration is $a(t) = v'(t) = 6t$.
5	What's an example of a problem where differential equations are used, and what's the general idea of solving them?	Differential equations model systems where the rate of change is involved. A classic example is population growth: $dP/dt = kP$, where P is population and k is the growth rate. Solving this equation often involves techniques like separation of variables or integrating factors to find the function $P(t)$ that describes the population over time.
6	How is calculus used in physics to describe forces, and what's a basic example?	Calculus is fundamental in physics. For instance, Newton's second law, $F = ma$, can be expressed using calculus. If mass (m) is constant, force is directly proportional to acceleration (the second derivative of position). In variable mass scenarios, the form $F = d(mv)/dt$ is used, highlighting the role of derivatives in understanding momentum changes.
