Decoding Partial Differential Equations: Worked Examples & Practical Applications

Partial differential equations (PDEs) might sound intimidating, but fear not! They're fundamental to understanding a wide range of phenomena, from fluid dynamics to heat transfer, and even the spread of diseases. This comprehensive guide will break down PDEs with worked examples, practical applications, and step-by-step instructions, empowering you to tackle these equations confidently.

Understanding the Fundamentals Before we dive into the examples, let's quickly revisit the core concepts. A partial differential equation is an equation that involves an unknown function of multiple variables and its partial derivatives. Unlike ordinary differential equations (ODEs), which deal with functions of a single variable, PDEs require handling multiple variables simultaneously. This is where the "partial" comes in – we're concerned with how the function changes with respect to *each* variable individually.

Common Types of PDEs PDEs are broadly categorized by their order and the type of derivatives they include:

- **First-Order PDEs:** These involve only first-order partial derivatives of the unknown function.
- **Second-Order PDEs:** These contain second-order partial derivatives. This category is critical because many physically relevant phenomena (heat flow, wave propagation) are described by second-order PDEs.

Worked Examples – Putting Theory into Practice Let's explore some real-world scenarios to solidify our understanding:

Example 1: The Heat Equation Imagine you're studying the temperature distribution within a metal rod. The heat equation describes how the temperature changes over time and space. Equation: $\partial u / \partial t = \alpha \nabla^2 u$ Where:

- $u(x,t)$ is the temperature at position x and time t
- α is the thermal diffusivity
- ∇^2 is the Laplacian operator (essentially, a combination of second-order partial derivatives).

Problem: A metal rod of length L is initially at a uniform temperature of 20°C . The ends of the rod are kept at 0°C . Find the temperature distribution $u(x,t)$ in the rod. **Solution:** (Step-by-step breakdown). This involves applying boundary conditions and solving using separation of variables. We can express the solution as a Fourier series. This solution would involve a series of trigonometric functions.

Example 2: The Wave Equation Consider a vibrating string. The wave equation describes how disturbances propagate along the string. Equation: $\partial^2 u / \partial t^2 = c^2 \partial^2 u / \partial x^2$ Where:

- $u(x,t)$ is the displacement of the string at position x and time t
- c is the wave speed.

Problem: A string of length L is fixed at both ends. Determine the possible vibrations of the string. **Solution:** The solution would involve using boundary conditions and the initial conditions of the string (like the initial shape and velocity). Again, we'd typically find a solution using trigonometric functions like sine and cosine.

How-to: Solving PDEs Solving PDEs often involves these techniques:

- **Separation of Variables:** This method is effective for certain types of PDEs with homogeneous boundary conditions. It simplifies the equation into smaller ODEs that can be solved independently.
- **Fourier Series and Transforms:** These techniques are invaluable for dealing with boundary conditions and simplifying the solutions of PDEs.
- **Numerical Methods:** When analytical solutions are not feasible, numerical methods (finite difference, finite element) provide approximate solutions. These methods are frequently employed in computer simulations.

Practical Applications PDEs are fundamental in many scientific and engineering disciplines:

- **Fluid Dynamics:** Modeling the flow of liquids and gases.
- **Electromagnetism:** Describing the behavior of electric and magnetic fields.
- **Quantum Mechanics:** Understanding the behavior of particles at the atomic level.
- **Heat Transfer:** Analyzing how heat flows through materials.

Unlocking the Mysteries: Partial Differential Equations Worked Examples Explained

Ever found yourself staring at an equation with more than one independent variable and feeling a delightful shiver of intellectual challenge? If so, you've likely encountered the fascinating world of Partial Differential Equations (PDEs). These mathematical titans are the bedrock of countless scientific and engineering disciplines, describing everything from the flow of heat and the spread of waves to the intricate dynamics of fluid mechanics and the evolution of financial markets. But let's be honest, while the applications are breathtaking, grasping PDEs can sometimes feel like trying to herd a flock of particularly elusive mathematical sheep. That's where worked examples come in. They're not just rote exercises; they're crucial stepping stones, illuminating the abstract concepts with concrete, step-by-step solutions. In this comprehensive guide, we'll dive deep into the realm of partial differential equations worked examples, demystifying common types and providing you with the confidence to tackle your own.

What Exactly ARE Partial Differential Equations?

Before we get our hands dirty with examples, let's quickly recap what makes a PDE tick. A differential equation relates a function with its derivatives. When that function depends on *multiple* independent variables (think time and space, or multiple spatial dimensions), and the derivatives are *partial* derivatives, we're in PDE territory. For instance, a simple ordinary differential equation (ODE) might describe the velocity of a falling object with respect to time: $\frac{dv}{dt} = -g$. Here, velocity v is a function of only one variable, time t . Now, imagine describing the temperature distribution across a metal plate. The temperature at any point depends on its position (say, x and y coordinates) *and* potentially on time t . This is where a PDE comes in, using partial derivatives like $\frac{\partial T}{\partial x}$, $\frac{\partial T}{\partial y}$, and $\frac{\partial T}{\partial t}$.

Why Are Worked Examples So Important for Learning PDEs?

The beauty of worked examples lies in their ability to bridge the gap between theory and practice. Here's why they're your best friends when learning PDEs:

- Concrete Illustration:** They take abstract mathematical concepts and bring them to life with tangible solutions. You see *how* a method is applied.
- Step-by-Step Guidance:** Each step in a worked example builds upon the previous one, providing a clear roadmap for solving similar problems. This is especially helpful for understanding complex solution techniques.
- Building Intuition:** By working through examples, you start to develop an intuition for how different PDEs behave and what their solutions represent physically.
- Identifying Common Pitfalls:** Worked examples often highlight common errors or tricky aspects of a problem, allowing you to learn from others' mistakes (and avoid making them yourself!).
- Developing Problem-Solving Strategies:** You begin to recognize patterns and develop effective strategies for approaching new PDE problems.
- Boosting Confidence:** Successfully solving a worked example provides a significant confidence boost, encouraging you to tackle more challenging problems.

The Pillars of PDE Study: Common Types and Worked Examples

To truly understand PDEs, we need to explore some of the most fundamental and frequently encountered types. Let's break them down with illustrative worked examples.

1. The Heat Equation: Describing Diffusion and Spreading

The heat equation is a cornerstone of physics, modeling how heat (or any diffusing quantity like concentration) spreads through a medium. In one spatial dimension, it's often written as: $\frac{\partial u}{\partial t} = \alpha \frac{\partial^2 u}{\partial x^2}$ where: $u(x, t)$ is the temperature (or concentration) at position x and time t . α is the thermal diffusivity (or diffusion coefficient), a positive constant representing how quickly the quantity diffuses.

Worked Example: A Simple 1D Heat Conduction Problem Let's

consider a long, thin rod of length L . Suppose its ends are kept at a constant temperature, and we want to find the temperature distribution $u(x, t)$ over time. **Problem Statement:** A rod of length π has its ends held at 0 temperature for all time $t \geq 0$. The initial temperature distribution along the rod is given by $u(x, 0) = \sin(x)$ for $0 \leq x \leq \pi$. Find the temperature distribution $u(x, t)$ for $t > 0$. Assume $\alpha = 1$. **Solution Steps:** 1. **Identify the PDE and Boundary/Initial Conditions:** PDE: $\frac{\partial u}{\partial t} = \frac{\partial^2 u}{\partial x^2}$ * Boundary Conditions (BCs): $u(0, t) = 0$ for $t \geq 0$, and $u(\pi, t) = 0$ for $t \geq 0$. * Initial Condition (IC): $u(x, 0) = \sin(x)$ for $0 \leq x \leq \pi$. 2. **Assume a Separable Solution:** We often use the method of separation of variables for linear, homogeneous PDEs like the heat equation. We assume a solution of the form $u(x, t) = X(x)T(t)$. 3. **Substitute into the PDE:** Substituting $u = XT$ into the PDE gives: $XT' = X''T$ Dividing by XT (assuming $X \neq 0$ and $T \neq 0$): $T'/T = X''/X$ 4. **Introduce the Separation Constant:** Since the left side depends only on t and the right side only on x , both sides must be equal to a constant, say $-\lambda$. $T'/T = -\lambda \implies T'(t) + \lambda T(t) = 0$ * $X''/X = -\lambda \implies X''(x) + \lambda X(x) = 0$ 5. **Solve the ODEs for $X(x)$ and $T(t)$:** **For $T(t)$:** The general solution is $T(t) = Ce^{-\lambda t}$, where C is a constant. **For $X(x)$:** The equation $X''(x) + \lambda X(x) = 0$ is a familiar ODE. The nature of its solution depends on λ . * If $\lambda \leq 0$, the only solution satisfying the BCs (as we'll see) is trivial ($X(x) \equiv 0$). * If $\lambda > 0$, let $\lambda = \omega^2$. The general solution is $X(x) = A \cos(\omega x) + B \sin(\omega x)$. 6. **Apply Boundary Conditions to $X(x)$:** $u(0, t) = X(0)T(t) = 0$. Since $T(t)$ is not identically zero, we need $X(0) = 0$. $X(0) = A \cos(0) + B \sin(0) = A = 0$. So, $X(x) = B \sin(\omega x)$. * $u(\pi, t) = X(\pi)T(t) = 0$. So, $X(\pi) = 0$. $X(\pi) = B \sin(\omega \pi) = 0$. For a non-trivial solution ($B \neq 0$), we need $\sin(\omega \pi) = 0$. This occurs when $\omega \pi = n\pi$ for integer $n \geq 1$. So, $\omega_n = n$, and $\lambda_n = \omega_n^2 = n^2$ for $n = 1, 2, 3, \dots$. The spatial eigenfunctions are $X_n(x) = B_n \sin(nx)$. 7. **Construct the General Solution (Superposition):** For each eigenvalue $\lambda_n = n^2$, we have a solution $u_n(x, t) = X_n(x)T_n(t) = B_n \sin(nx) e^{-n^2 t}$. Since the heat equation is linear and homogeneous, the general solution is a superposition of these individual solutions: $u(x, t) = \sum_{n=1}^{\infty} B_n \sin(nx) e^{-n^2 t}$. 8. **Apply the Initial Condition to Determine Coefficients:** Now we use $u(x, 0) = \sin(x)$: $u(x, 0) = \sum_{n=1}^{\infty} B_n \sin(nx) = \sin(x)$. By comparing this to the Fourier sine series representation, we can identify the coefficients. In this case, it's straightforward: For $n=1$, $B_1 = 1$. For $n > 1$, $B_n = 0$. 9. **Write the Final Solution:** $u(x, t) = \sin(x) e^{-t}$. **Key Takeaways from this Example:** * The method of separation of variables is a powerful tool. * Boundary conditions dictate the possible forms of spatial solutions (eigenfunctions). * Initial conditions determine the specific linear combination (coefficients) of these solutions. * The $e^{-n^2 t}$ term shows that the temperature distribution decays to zero over time, as expected due to the fixed-temperature boundaries.

2. The Wave Equation: Modeling Oscillations and Propagation

The wave equation describes phenomena like vibrating strings, sound waves, and electromagnetic waves. In one spatial dimension, it looks like this: $\frac{\partial^2 u}{\partial t^2} = c^2 \frac{\partial^2 u}{\partial x^2}$ where: * $u(x, t)$ is the displacement (or amplitude) of the wave at position x and time t . * c is the wave speed, a positive constant. **Worked Example: A Vibrating String** Consider a string of length L fixed at both ends. We want to describe its motion. **Problem Statement:** A string of length π is fixed at both ends. It is initially plucked so that its initial displacement is $u(x, 0) = \sin(x)$ and its initial velocity is $\frac{\partial u}{\partial t}(x, 0) = 0$ for $0 \leq x \leq \pi$. Assume the wave speed $c = 1$. Find the displacement $u(x, t)$ for $t > 0$. **Solution Steps:** 1. **Identify the PDE and Boundary/Initial Conditions:** PDE: $\frac{\partial^2 u}{\partial t^2} = \frac{\partial^2 u}{\partial x^2}$ * BCs: $u(0, t) = 0$ and $u(\pi, t) = 0$ for $t \geq 0$. * ICs: $u(x, 0) = \sin(x)$ and $\frac{\partial u}{\partial t}(x, 0) = 0$ for $0 \leq x \leq \pi$. 2. **Separation of Variables:** Assume $u(x, t) = X(x)T(t)$. Substituting into the PDE: $XT'' = X''T$ Dividing by XT : $T''/T = X''/X = -\lambda$ (where λ is a separation constant). 3. **Solve ODEs and Apply BCs to $X(x)$:** * $X''(x) + \lambda X(x) = 0$. As with the heat equation, for non-trivial solutions satisfying $X(0)=0$ and $X(\pi)=0$, we need $\lambda_n = n^2$ for $n=1, 2, 3, \dots$. * The spatial eigenfunctions are $X_n(x) = A_n \sin(nx)$. 4. **Solve the ODE for $T(t)$:** * $T''(t) + \lambda_n T(t) = 0 \implies T_n''(t) + n^2 T_n(t) = 0$. * The general solution for $T_n(t)$ is $T_n(t) = B_n \cos(nt) + C_n \sin(nt)$. 5. **Construct the General Solution (Superposition):** Combining $X_n(x)$ and $T_n(t)$ for each n : $u(x, t) = \sum_{n=1}^{\infty} X_n(x)T_n(t) = \sum_{n=1}^{\infty} (A_n \sin(nx)) (B_n \cos(nt) + C_n \sin(nt))$. We can absorb $A_n B_n$ into B_n and $A_n C_n$, so let's write it as: $u(x, t) = \sum_{n=1}^{\infty} \sin(nx) (B_n \cos(nt) + C_n \sin(nt))$. 6. **Apply Initial Conditions:** **IC 1:** $u(x, 0) = \sin(x)$ * $u(x, 0) = \sum_{n=1}^{\infty} \sin(nx) (B_n \cos(0) + C_n \sin(0)) = \sum_{n=1}^{\infty} B_n \sin(nx)$. Comparing with $u(x, 0) = \sin(x)$, we get $B_1 = 1$ and $B_n = 0$ for $n > 1$. **IC 2:** $\frac{\partial u}{\partial t}(x, 0) = 0$ * First, find the time derivative of $u(x, t)$: $\frac{\partial u}{\partial t}(x, t) = \sum_{n=1}^{\infty} \sin(nx) (-n B_n \sin(nt) + n C_n \cos(nt))$. Now, set $t=0$: $\frac{\partial u}{\partial t}(x, 0) = \sum_{n=1}^{\infty} \sin(nx) (-n B_n \sin(0) + n C_n \cos(0)) = \sum_{n=1}^{\infty} n C_n \sin(nx)$. We are given $\frac{\partial u}{\partial t}(x, 0) = 0$. So, $\sum_{n=1}^{\infty} n C_n \sin(nx) = 0$. This implies $n C_n = 0$ for all $n \geq 1$. Since $n \neq 0$, we must have $C_n = 0$ for all n . 7. **Write the Final Solution:** With $B_1 = 1$ and $B_n = 0$ for $n > 1$, and all $C_n = 0$, the

solution becomes: $u(x, t) = \sin(x) (1 \cdot \cos(1 \cdot t) + 0 \cdot \sin(1 \cdot t)) = \sin(x) \cos(t)$. **Key Takeaways from this Example:** * The wave equation requires two initial conditions (displacement and velocity) due to its second-order nature in time. * The solution involves both sine and cosine terms in time, representing oscillations. * The $\cos(nt)$ and $\sin(nt)$ terms in the time solution describe the oscillatory motion of the string.

3. Laplace's Equation: Steady-State Problems and Equilibrium

Laplace's equation describes systems in a steady state, where quantities are no longer changing with time. It's fundamental in electrostatics, steady fluid flow, and steady-state heat conduction. In two spatial dimensions, it's: $\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0$ where $u(x, y)$ is the quantity of interest (e.g., electric potential, temperature). **Worked Example: Steady-State Temperature in a Rectangle** **Problem Statement:** Find the steady-state temperature distribution $u(x, y)$ in a rectangular plate defined by $0 \leq x \leq a$ and $0 \leq y \leq b$, given that the temperature on the edges is specified. Let's consider the case where: * $u(x, 0) = 0$ for $0 \leq x \leq a$ (bottom edge) * $u(x, b) = 0$ for $0 \leq x \leq a$ (top edge) * $u(0, y) = 0$ for $0 \leq y \leq b$ (left edge) * $u(a, y) = \sin(\pi y / b)$ for $0 \leq y \leq b$ (right edge) **Solution Steps:** 1. **Identify the PDE and Boundary Conditions:** * PDE: $\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0$ * BCs as listed above. 2. **Separation of Variables:** Assume $u(x, y) = X(x)Y(y)$. Substituting into Laplace's equation: $X''Y + XY'' = 0$ Dividing by XY : $X''/X + Y''/Y = 0$ $X''/X = -Y''/Y = \lambda$ (where λ is the separation constant). 3. **Solve ODEs for $X(x)$ and $Y(y)$:** **For $Y(y)$:** $Y''(y) - \lambda Y(y) = 0$. The BCs for Y are $Y(0) = 0$ and $Y(b) = 0$. This leads to $\lambda_n = -(n\pi/b)^2$ for $n = 1, 2, 3, \dots$. The spatial solutions for Y are $Y_n(y) = \sin(n\pi y / b)$. **For $X(x)$:** $X''(x) - \lambda_n X(x) = 0$ implies $X''(x) - (n\pi/b)^2 X(x) = 0$. The general solution for $X_n(x)$ is $X_n(x) = A_n \cosh(n\pi x / b) + B_n \sinh(n\pi x / b)$. 4. **Apply Remaining Boundary Conditions to $X(x)$:** * $u(0, y) = X(0)Y(y) = 0$. Since $Y(y)$ is not identically zero, we need $X(0) = 0$. $X(0) = A_n \cosh(0) + B_n \sinh(0) = A_n = 0$. So, $X_n(x) = B_n \sinh(n\pi x / b)$. 5. **Construct the General Solution (Superposition):** $u(x, y) = \sum_{n=1}^{\infty} X_n(x)Y_n(y) = \sum_{n=1}^{\infty} B_n \sinh(n\pi x / b) \sin(n\pi y / b)$. 6. **Apply the Final Boundary Condition:** $u(a, y) = \sin(\pi y / b)$. $u(a, y) = \sum_{n=1}^{\infty} B_n \sinh(n\pi a / b) \sin(n\pi y / b) = \sin(\pi y / b)$. This is a Fourier sine series. Comparing coefficients: * For $n=1$: $B_1 \sinh(\pi a / b) = 1$ implies $B_1 = 1 / \sinh(\pi a / b)$. * For $n > 1$: $B_n \sinh(n\pi a / b) = 0$. Since $\sinh(n\pi a / b) \neq 0$ for $n \geq 1$, we have $B_n = 0$ for $n > 1$. 7. **Write the Final Solution:** $u(x, y) = \frac{1}{\sinh(\pi a / b)} \sinh(\pi x / b) \sin(\pi y / b)$. **Key Takeaways from this Example:** * Laplace's equation often involves boundary conditions specified on all sides of the domain. * The hyperbolic functions ($\cosh$, $\sinh$) appear in solutions to Laplace's equation when separation of variables is used along an axis where there are no homogeneous boundary conditions. * This solution represents the equilibrium temperature distribution, where no heat is flowing in or out of the plate.

Understanding Partial Differential Equations Through Worked Examples Partial differential equations, or PDEs, form a cornerstone of modern applied mathematics, modeling phenomena across physics, engineering, biology, and finance. Unlike ordinary differential equations that describe systems evolving over time in a single dimension, PDEs capture how quantities change across multiple variables—such as space and time—making them indispensable for describing continuous, dynamic systems. This article explores key worked examples of PDEs, shedding light on their structure, significance, and impact.

The Essence of Partial Differential Equations At their core, PDEs relate a function of several independent variables to its partial derivatives. A simple example is the one-dimensional heat equation, which models how temperature diffuses through a rod over time. Written as $\partial u / \partial t = \alpha \partial^2 u / \partial x^2$, where $u(x,t)$ represents temperature and α is thermal diffusivity, this equation reveals how initial heat distributions evolve. The left side captures the rate of change in time, while the right side describes spatial curvature—highlighting how steep temperature gradients drive heat flow. Such equations embody the principle that change arises from spatial variation, a fundamental insight across sciences.

Classic PDEs and Their Real-World Applications Beyond the heat equation, PDEs encompass a rich class of models. The wave equation, $\partial^2 u / \partial t^2 = c^2 \partial^2 u / \partial x^2$, governs wave propagation—from

sound in air to vibrations in strings. Solving it reveals how disturbances travel at speed c , offering predictions crucial for acoustics, telecommunications, and seismic analysis. In fluid dynamics, the Navier-Stokes equations describe motion in liquids and gases, enabling simulations of airflow over wings or ocean currents. These applications underscore PDEs' role as predictive tools, translating abstract mathematics into actionable insights. Another vital family is elliptic PDEs, such as Laplace's equation, $\nabla^2 u = 0$. Used in electrostatics and steady-state heat distribution, these equations define equilibrium conditions—where no change occurs over time. Solving them reveals potential fields, guiding engineers in designing electrical circuits or insulating materials. Each PDE type—parabolic, hyperbolic, elliptic—corresponds to distinct physical behaviors, reinforcing the need to match models to real-world conditions.

Key Insights and Problem-Solving Strategies Working through PDE examples cultivates a deeper understanding of boundary and initial conditions, essential for meaningful solutions. For instance, in the heat equation, specifying fixed temperatures at both ends of a rod determines the temperature profile's evolution uniquely. Similarly, the wave equation requires initial displacement and velocity to fully specify motion. These constraints shape solution behavior, demonstrating that PDEs are not just mathematical abstractions but tools tightly linked to physical reality. Numerical methods, such as finite difference schemes, allow solving complex PDEs when analytical solutions are elusive. These approaches approximate derivatives and iteratively compute

solutions, enabling simulations of intricate systems like turbulent flows or chemical transport. Mastery of these techniques empowers researchers and engineers to tackle real-world problems where exact solutions remain out of reach.

The Broader Impact and Future Outlook The influence of partial differential equations extends far beyond theoretical mathematics. In climate science, PDE-based models simulate atmospheric dynamics, informing climate projections and policy decisions. In medical imaging, diffusion tensor PDEs map neural pathways, advancing neuroscience. As computational power grows, so does the scale and precision of PDE simulations, unlocking new frontiers in artificial intelligence, quantum computing, and personalized medicine. Looking ahead, the integration of PDEs with data-driven methods promises transformative advances. Hybrid models combining classical PDE frameworks with machine learning offer enhanced predictive accuracy and reduced computational cost. This synergy fuels innovation across disciplines, reinforcing PDEs as a dynamic and evolving field. Understanding partial differential equations through worked examples reveals not only their mathematical elegance but also their indispensable role in shaping technology and science. From simulating the spread of heat to predicting weather patterns, PDEs continue to illuminate the hidden laws governing our physical world—bridging theory and application with precision and power.

Partial Differential Equations (PDEs) are fundamental to understanding a vast array of phenomena in science, engineering,

economics, and beyond. From modeling the flow of heat and fluids to describing wave propagation and the behavior of subatomic particles, PDEs provide the mathematical language for describing systems that change over space and time. While the theoretical underpinnings of PDEs can be complex, working through practical examples is crucial for developing intuition and mastering problem-solving techniques. This article delves into the world of 'partial differential equations worked examples', offering a comprehensive guide to their application and solution.

The Essence of Partial Differential Equations

Before diving into worked examples, it's essential to grasp what distinguishes PDEs from Ordinary Differential Equations (ODEs). ODEs involve functions of a single independent variable and their derivatives, whereas PDEs involve functions of two or more independent variables and their partial derivatives. This increase in dimensionality opens up a universe of possibilities for modeling more intricate systems. Common independent variables include time (t) and spatial coordinates (x, y, z).

The 'partial differential equations worked examples' we will explore will illuminate how these equations capture complex relationships. For instance, the heat equation describes how temperature distributes over time and space, involving partial derivatives with respect to time and spatial variables. Similarly, the wave equation, a cornerstone in physics, models phenomena like vibrating strings and electromagnetic waves, again requiring partial derivatives with respect to both time and space.

Classifying Partial Differential Equations

The approach to solving PDEs often depends on their classification. Understanding these categories is a vital first step in tackling any 'partial differential equations worked examples'. The most common classification is based on the behavior of the second-order partial derivatives of the dependent variable. For a general second-order linear PDE in two independent variables $u(x, y)$:

$$Au_{xx} + Bu_{xy} + Cu_{yy} + Du_x + Eu_y + Fu + G = 0$$

where A, B, C, D, E, F, G are functions of x and y . The classification depends on the discriminant $\Delta = B^2 - 4AC$:

1. **Elliptic Equations:** $\Delta < 0$. These typically describe steady-state phenomena, such as equilibrium temperature distributions or electrostatic potentials. Laplace's equation ($\nabla^2 u = 0$) and Poisson's equation ($\nabla^2 u = f$) are prime examples.
2. **Parabolic Equations:** $\Delta = 0$. These usually model diffusion processes, like heat conduction or mass transport. The heat equation ($u_t = \alpha \nabla^2 u$) is the quintessential parabolic PDE.
3. **Hyperbolic Equations:** $\Delta > 0$. These describe wave-like phenomena, where disturbances propagate through a medium. The wave equation ($u_{tt} = c^2 \nabla^2 u$) is the most recognized hyperbolic PDE.

Exploring 'partial differential equations worked examples' within these categories will solidify understanding of their distinct characteristics and solution methodologies.

Common Solution Techniques for PDEs

Several powerful techniques are employed to solve PDEs. Each has its strengths and is best suited for specific types of equations and boundary conditions. Familiarizing yourself with these methods is key to effectively engaging with 'partial differential equations worked examples'.

Separation of Variables

This is one of the most fundamental and widely applicable techniques, particularly for linear, homogeneous PDEs on regular domains with simple boundary conditions. The core idea is to assume that the solution $u(x, t)$ can be expressed as a product of functions, each depending on only one independent variable. For example, $u(x, t) = X(x)T(t)$. Substituting this into the PDE leads to a set of ODEs, which are generally easier to solve.

Worked Example: The 1D Heat Equation

Let's consider the 1D heat equation on a finite rod of length L , with insulated ends, and an initial temperature distribution. $\frac{\partial u}{\partial t} = \alpha \frac{\partial^2 u}{\partial x^2}$, $\quad 0 < x < L, \quad t > 0$

Boundary Conditions: $\frac{\partial u}{\partial x}(0, t) = 0, \quad \frac{\partial u}{\partial x}(L, t) = 0$

Initial Condition: $u(x, 0) = f(x)$

Here, α is the thermal diffusivity. We seek 'partial differential equations worked examples' that demonstrate how to solve this classic problem.

Assume $u(x, t) = X(x)T(t)$. Substituting into the PDE gives:

$$X(x)T'(t) = \alpha X''(x)T(t)$$

Separating variables:

$$\frac{T'(t)}{\alpha T(t)} = \frac{X''(x)}{X(x)} = -\lambda$$

Here, $-\lambda$ is the separation constant. This gives us two ODEs:

1. $T'(t) = -\lambda \alpha T(t)$ (leading to $T(t) = C e^{-\lambda \alpha t}$)

2. $X''(x) + \lambda X(x) = 0$

Now, we must consider the boundary conditions. For the boundary conditions $\frac{\partial u}{\partial x}(0, t) = 0$ and $\frac{\partial u}{\partial x}(L, t) = 0$, we have $X'(0)T(t) = 0$ and $X'(L)T(t) = 0$. Since $T(t)$ is not identically zero, we require $X'(0) = 0$ and $X'(L) = 0$. This transforms the spatial ODE into a Sturm-Liouville problem.

The solutions to $X''(x) + \lambda X(x) = 0$ with $X'(0)=0$ and $X'(L)=0$ depend on the sign of λ .

1. If $\lambda = 0$: $X''(x) = 0 \implies X(x) = Ax + B$. Then $X'(x) = A$. $X'(0)=0 \implies A=0$. So $X(x) = B$. This is a valid solution.
2. If $\lambda < 0$ (let $\lambda = -\mu^2$): $X''(x) - \mu^2 X(x) = 0 \implies X(x) = A \cosh(\mu x) + B \sinh(\mu x)$. Then $X'(x) = A \mu \sinh(\mu x) + B \mu \cosh(\mu x)$. $X'(0)=0 \implies B=0$. So $X(x) = A \cosh(\mu x)$. $X'(L)=0 \implies A \mu \sinh(\mu L) = 0$. Since $\mu \neq 0$ and $\sinh(\mu L) \neq 0$, we must have $A=0$, leading to the trivial solution $X(x)=0$.
3. If $\lambda > 0$ (let $\lambda = \mu^2$): $X''(x) + \mu^2 X(x) = 0 \implies X(x) = A \cos(\mu x) + B \sin(\mu x)$. Then $X'(x) = -A \mu \sin(\mu x) + B \mu \cos(\mu x)$. $X'(0)=0 \implies B=0$. So $X(x) = A \cos(\mu x)$. $X'(L)=0 \implies -A \mu \sin(\mu L) = 0$.

For non-trivial solutions, we need $\sin(\mu L) = 0$, which implies $\mu L = n\pi$ for $n=1, 2, 3, \dots$. So $\mu_n = \frac{n\pi}{L}$ and $\lambda_n = \mu_n^2 = \left(\frac{n\pi}{L}\right)^2$. The corresponding solutions are $X_n(x) = \cos\left(\frac{n\pi x}{L}\right)$.

The eigenvalues are $\lambda_0 = 0$ with eigenfunction $X_0(x) = 1$, and $\lambda_n = \left(\frac{n\pi}{L}\right)^2$ for $n=1, 2, 3, \dots$ with eigenfunctions $X_n(x) = \cos\left(\frac{n\pi x}{L}\right)$.

The corresponding time solutions are $T_0(t) = e^{0 \cdot t} = 1$ and $T_n(t) = e^{-\lambda_n \alpha t} = e^{-\left(\frac{n\pi}{L}\right)^2 \alpha t}$.

The general solution is a superposition of these fundamental solutions:

$$u(x, t) = A_0 X_0(x)T_0(t) + \sum_{n=1}^{\infty} A_n X_n(x)T_n(t)$$

$$u(x, t) = A_0 + \sum_{n=1}^{\infty} A_n \cos\left(\frac{n\pi x}{L}\right) e^{-\left(\frac{n\pi}{L}\right)^2 \alpha t}$$

Now, we use the initial condition $u(x, 0) = f(x)$ to find the coefficients A_n :

$$f(x) = A_0 + \sum_{n=1}^{\infty} A_n \cos\left(\frac{n\pi x}{L}\right)$$

This is a Fourier cosine series expansion of $f(x)$. The coefficients are found using the orthogonality of cosine functions:

$$A_0 = \frac{1}{L} \int_0^L f(x) dx$$

$$A_n = \frac{2}{L} \int_0^L f(x) \cos\left(\frac{n\pi x}{L}\right) dx$$

$\quad \text{for } n \geq 1$

This 'partial differential equations worked examples' demonstrates how separation of variables, combined with Fourier series, provides a complete solution to a common PDE problem.

Fourier Transforms

When dealing with PDEs on infinite or semi-infinite domains, Fourier transforms are often more suitable than Fourier series. The Fourier transform converts a PDE into an ODE in the transform domain, which can then be solved. The inverse Fourier transform is then used to obtain the solution in the original domain.

Worked Example: The 1D Heat Equation on an Infinite Rod

Consider the 1D heat equation on an infinite rod with an initial temperature distribution $u(x, 0) = f(x)$. $\frac{\partial u}{\partial t} = \alpha \frac{\partial^2 u}{\partial x^2}$, $-\infty < x < \infty$, $t > 0$ Initial Condition: $u(x, 0) = f(x)$ We assume that $u(x, t) \rightarrow 0$ as $|x| \rightarrow \infty$ and $t \rightarrow \infty$. This problem is a prime candidate for 'partial differential equations worked examples' utilizing Fourier transforms.

Let $\hat{u}(\xi, t)$ be the Fourier transform of $u(x, t)$ with respect to x : $\hat{u}(\xi, t) = \mathcal{F}\{u(x, t)\} = \int_{-\infty}^{\infty} u(x, t) e^{-i \xi x} dx$

The Fourier transform of the spatial derivative is:

$$\mathcal{F}\left\{\frac{\partial^2 u}{\partial x^2}\right\} = (i\xi)^2 \hat{u}(\xi, t) = -\xi^2 \hat{u}(\xi, t)$$

The Fourier transform of the time derivative is:

$$\mathcal{F}\left\{\frac{\partial u}{\partial t}\right\} = \frac{d}{dt} \hat{u}(\xi, t)$$

Applying the Fourier transform to the PDE:

$$\frac{d}{dt} \hat{u}(\xi, t) = -\alpha \xi^2 \hat{u}(\xi, t)$$

This is an ODE in t for each ξ . The solution is:

$$\hat{u}(\xi, t) = C(\xi) e^{-\alpha \xi^2 t}$$

The constant of integration $C(\xi)$ is determined by the initial condition. Taking the Fourier transform of $u(x, 0) = f(x)$:

$$\hat{u}(\xi, 0) = \mathcal{F}\{f(x)\} = \hat{f}(\xi)$$

So, at $t=0$, $C(\xi) e^0 = \hat{f}(\xi)$, which means $C(\xi) = \hat{f}(\xi)$.

Thus, the transformed solution is:

$$\hat{u}(\xi, t) = \hat{f}(\xi) e^{-\alpha \xi^2 t}$$

To find $u(x, t)$, we need to take the inverse Fourier transform.

We recognize that $e^{-\alpha \xi^2 t}$ is the Fourier transform of a Gaussian function. Specifically, the inverse Fourier transform of $e^{-a \xi^2}$ is $\sqrt{\frac{\pi}{a}} e^{-x^2/(4a)}$. In our case, $a = \alpha t$. The Fourier transform of $\frac{1}{\sqrt{4\pi \alpha t}} e^{-x^2/(4\alpha t)}$ is $e^{-\alpha \xi^2 t}$.

Using the convolution theorem for Fourier transforms, which states that $\mathcal{F}\{f * g\} = \mathcal{F}\{f\} \mathcal{F}\{g\}$, we can express $u(x, t)$ as the convolution of $f(x)$ and the inverse transform of $e^{-\alpha \xi^2 t}$:

$$u(x, t) = \mathcal{F}^{-1}\{\hat{f}(\xi) e^{-\alpha \xi^2 t}\} = f(x) *$$

$$\mathcal{F}^{-1}\{e^{-\alpha \xi^2 t}\}$$

The inverse transform of $e^{-\alpha \xi^2 t}$ is $\frac{1}{\sqrt{4\pi \alpha t}} e^{-x^2/(4\alpha t)}$, often called the heat kernel or fundamental solution.

Therefore, the solution is:

$$u(x, t) = \int_{-\infty}^{\infty} f(y) \frac{1}{\sqrt{4\pi \alpha t}} e^{-\frac{(x-y)^2}{4\alpha t}} dy$$

This is a classic result for the heat equation on an infinite domain, and it's a crucial 'partial differential equations worked examples' that highlights the power of Fourier analysis.

Method of Characteristics

This technique is particularly useful for first-order PDEs and hyperbolic second-order PDEs. It involves transforming the PDE into a system of ODEs along characteristic curves. Along these curves, the PDE simplifies, allowing for integration.

Worked Example: The 1D Transport Equation

Consider the 1D transport (or advection) equation:

$$\frac{\partial u}{\partial t} + c \frac{\partial u}{\partial x} = 0$$

where c is a constant velocity, and $u(x, 0) = f(x)$ is the initial condition. This is a simple but important PDE often used to model advection processes. This example illustrates a foundational application of 'partial differential equations worked examples' via characteristics.

We look for curves in the (x, t) plane along which the solution u is constant. Consider a curve parameterized by s , such that

$x=x(s)$ and $t=t(s)$. The total derivative of u along this curve is:

$$\frac{du}{ds} = \frac{\partial u}{\partial t} \frac{dt}{ds} + \frac{\partial u}{\partial x} \frac{dx}{ds}$$

We want this to be zero. Comparing this with the PDE

$\frac{\partial u}{\partial t} + c \frac{\partial u}{\partial x} = 0$, we can set:

$$\frac{dt}{ds} = 1$$

$$\frac{dx}{ds} = c$$

These are the characteristic equations. Integrating them:

$$t = s + t_0$$

$$x = cs + x_0$$

where t_0 and x_0 are constants of integration. We can eliminate s . From $t = s + t_0$, $s = t - t_0$. Substituting into the equation for x : $x = c(t - t_0) + x_0$, which can be rewritten as $x - ct = x_0 - ct_0$. Let $C = x_0 - ct_0$. Then the characteristic curves are given by $x - ct = C$. Along these curves, u is constant.

Now, consider the initial condition $u(x, 0) = f(x)$. At $t=0$, the characteristic curves are $x = C$. So, for a point (x, t) , it lies on the characteristic curve $x' - ct' = C$. To find $u(x, t)$, we trace back along this characteristic to the initial line $t=0$. At $t'=0$, the characteristic is $x' = C$. If the point (x, t) is on the characteristic $x - ct = C$, then at $t'=0$, the corresponding x' is C . So, $x' = x - ct$. Since u is constant along the characteristic, $u(x, t) = u(x', 0) = f(x')$.

Therefore, the solution is:

$$u(x, t) = f(x - ct)$$

This result indicates that the initial profile $f(x)$ simply propagates to the right with speed c without changing its shape. This is a key insight from 'partial differential equations worked examples' using the method of characteristics.

Laplace Transforms

Laplace transforms are another powerful tool, particularly effective for initial value problems involving linear ODEs and PDEs, especially those with constant coefficients. Similar to Fourier transforms, they convert differential equations into algebraic equations in the Laplace domain.

Worked Example: A Simple PDE with Laplace Transform

Consider the problem:

$$\frac{\partial u}{\partial t} = \frac{\partial^2 u}{\partial x^2} - u, \quad x > 0, \quad t > 0$$

with boundary conditions:

$$u(0, t) = e^{-t}$$

$$u(x, 0) = 0$$

and assuming $u(x, t) \rightarrow 0$ as $x \rightarrow \infty$. This is a semi-infinite rod problem with a specific boundary forcing. This is a good candidate for 'partial differential equations worked examples' involving Laplace transforms.

Let $\bar{u}(x, s) = \mathcal{L}\{u(x, t)\}$ be the Laplace transform

of $u(x, t)$ with respect to t . $\mathcal{L}\left\{\frac{\partial u}{\partial t}\right\} = s\bar{u}(x, s) - u(x, 0) = s\bar{u}(x, s) - 0 = s\bar{u}(x, s)$

$$\mathcal{L}\left\{\frac{\partial^2 u}{\partial x^2}\right\} = \frac{\partial^2}{\partial x^2} \bar{u}(x, s)$$

$$\mathcal{L}\{u\} = \bar{u}(x, s)$$

Transforming the PDE:

$$s\bar{u}(x, s) = \frac{\partial^2 \bar{u}}{\partial x^2}(x, s) - \bar{u}(x, s)$$

Rearranging gives an ODE in x for $\bar{u}(x, s)$:

$$\frac{d^2 \bar{u}}{dx^2}(x, s) - (s+1)\bar{u}(x, s) = 0$$

The boundary condition at $x=0$ transforms to:

$$\mathcal{L}\{u(0, t)\} = \mathcal{L}\{e^{-t}\} = \frac{1}{s+1}$$

So, $\bar{u}(0, s) = \frac{1}{s+1}$. The condition at infinity transforms to $\bar{u}(x, s) \rightarrow 0$ as $x \rightarrow \infty$.

The general solution to the ODE $\frac{d^2 \bar{u}}{dx^2} - (s+1)\bar{u} = 0$ is:

$$\bar{u}(x, s) = A(s) e^{\sqrt{s+1} x} + B(s) e^{-\sqrt{s+1} x}$$

Using the condition $\bar{u}(x, s) \rightarrow 0$ as $x \rightarrow \infty$, we must have $A(s) = 0$ (assuming $s > -1$ for $\sqrt{s+1}$ to be real and positive for large s). So:

$$\bar{u}(x, s) = B(s) e^{-\sqrt{s+1} x}$$

Now, apply the boundary condition at $x=0$: $\bar{u}(0, s) = B(s) e^0 = B(s)$ So, $B(s) = \frac{1}{s+1}$. Therefore:

$$\bar{u}(x, s) = \frac{1}{s+1} e^{-\sqrt{s+1} x}$$

To find $u(x, t)$, we need to find the inverse Laplace transform of

this expression. This is not a standard transform. However, it is known that:

$$\mathcal{L}^{-1}\left\{\frac{1}{s+1} e^{-\sqrt{s+1} x}\right\} = e^{-t} \operatorname{erfc}\left(\frac{x}{2\sqrt{t}}\right)$$

where erfc is the complementary error function. This gives the final solution:

$$u(x, t) = e^{-t} \operatorname{erfc}\left(\frac{x}{2\sqrt{t}}\right)$$

This 'partial differential equations worked examples' demonstrates how Laplace transforms can handle boundary conditions and initial values effectively.

Numerical Methods

For many PDEs, analytical solutions are not feasible or even possible. In such cases, numerical methods are indispensable. These methods approximate the solution at discrete points in space and time. Popular techniques include:

1. **Finite Difference Methods (FDM):** Approximating derivatives with finite differences.
2. **Finite Element Methods (FEM):** Discretizing the domain into small elements and approximating the solution within each element.
3. **Finite Volume Methods (FVM):** Integrating the PDE over control volumes.

These numerical approaches are crucial for real-world engineering and scientific applications, allowing us to tackle complex geometries and nonlinearities. Exploring 'partial differential equations worked examples' involving numerical

solutions would require delving into specific algorithms and computational implementation.

The Importance of Initial and Boundary Conditions

A recurring theme in all 'partial differential equations worked examples' is the critical role of initial and boundary conditions. These conditions provide the specific information about the system being modeled and are essential for obtaining a unique solution.

- 1. Initial Conditions (ICs): Specify the state of the system at the starting time ($t=0$).**
- 2. Boundary Conditions (BCs): Specify the behavior of the solution at the boundaries of the spatial domain. These can be Dirichlet (specifying the value of the solution), Neumann (specifying the derivative of the solution, often related to flux), or Robin (a combination of Dirichlet and Neumann).**

The type and number of conditions required depend on the order of the PDE and the number of independent variables.

Questions & Answers About partial differential equations worked examples

No	Question	Answer
1	What's the first step to solving a typical PDE like the heat equation?	For many PDEs, including the heat equation, the first step often involves identifying the type of equation (parabolic, hyperbolic, elliptic) and then choosing an appropriate solution method like separation of variables, Fourier transforms, or numerical methods.
2	Can you show a simple worked example of the wave equation?	A classic example is a vibrating string. By applying separation of variables to the wave equation ($\partial^2 u / \partial t^2 = c^2 \partial^2 u / \partial x^2$) and using boundary and initial conditions, we can derive a general solution as a Fourier series representing the superposition of standing waves.
3	What are some common boundary conditions encountered in PDE examples?	Common boundary conditions include Dirichlet (specifying the value of the solution on the boundary), Neumann (specifying the derivative of the solution on the boundary), and Robin (a linear combination of the solution and its derivative on the boundary).
4	How do numerical methods like finite differences simplify PDE problems?	Finite difference methods discretize the domain and approximate derivatives with algebraic differences. This transforms the PDE into a system of linear (or non-linear) algebraic equations that can be solved computationally, making them practical for complex geometries and conditions.
5	What's the significance of initial conditions in worked PDE examples?	Initial conditions provide the starting state of the system. For time-dependent PDEs like the heat or wave equation, they are crucial for determining a unique particular solution from the general solution.

6	Are there worked examples of Laplace's equation and where are they used?	Yes! Laplace's equation ($\nabla^2 u = 0$) appears in steady-state heat distribution, electrostatics, and fluid flow. Worked examples often involve finding the temperature distribution in a plate or the electric potential in a region, frequently solved using separation of variables in rectangular or polar coordinates.
7	What's the difference between analytical and numerical solutions in PDE examples?	Analytical solutions provide an exact formula for the solution, often derived using techniques like separation of variables. Numerical solutions are approximations obtained using computational methods (like finite differences or finite elements) and are essential when analytical solutions are difficult or impossible to find.
8	How does the method of characteristics work for first-order PDEs?	The method of characteristics transforms a first-order PDE into a system of ordinary differential equations (ODEs) along characteristic curves. Solving these ODEs allows us to trace the solution from known initial or boundary data.
9	What are some common pitfalls to watch out for in PDE worked examples?	Common pitfalls include incorrectly applying boundary/initial conditions, algebraic errors in manipulation, misunderstanding the physical meaning of the solution, and choosing an inappropriate solution method for the given PDE and conditions.
10	Where can I find good worked examples for PDEs online?	Reputable sources include university math department websites (often with course notes and problem sets), online educational platforms like Khan Academy and Coursera, and dedicated math forums like Stack Exchange's Mathematics section. Textbooks also offer extensive worked examples.
